Objectives & Methodology
This research was undertaken to determine how U.S. adults use antibiotics and, in particular, how the antibiotics are procured.

Specific objectives included:

- Determine the proportion of U.S. adults who have used antibiotics in the past 12 months
- Determine the prevalence of improper means of procuring antibiotics
  - Asking a health care provider for antibiotics
  - Obtaining antibiotics from a source other than a health care provider
  - Obtaining a prescription without an office visit
- Identify practices in using antibiotics and other medications
- Identify segments of the population who are most likely to improperly procure or use antibiotics and other medications
- Explore perceptions of antibiotics
  - Ability to correctly identify antibiotics
  - Ability to identify situations in which antibiotics can be effective
  - Awareness of antibiotic resistance
  - Concerns regarding antibiotics, as compared to concerns about other health issues
919 U.S. adults were interviewed by telephone for this research.

- The sample for the survey consisted of a representative cross-section of U.S. adults, plus an over-sampling of Hispanic and African American adults, who were under-represented in initial interviewing.

- People who were contacted were eligible to complete the survey if they had taken an antibiotic to treat an illness within the previous 12 months.
  - For this reason, survey results can only be considered representative of U.S. adults who have recently taken antibiotics, and not all U.S. adults.
  - Some demographic information was obtained from those who were not eligible for the survey as input to the weighting of the survey results.

- Interviewing was conducted between September 6 and November 9, 2006.
  - Interviews averaged 17 minutes in length.
  - Respondents were told that the survey was sponsored by a non-profit public health organization, and APUA was named if the respondent asked.

- A two-step process was used to appropriately weight the survey responses to reflect the U.S. population by gender, ethnicity, and age.
  - Population statistics were take from the U.S. Census Bureau’s 2005 Population Estimates.
  - First, respondents who completed the screening questions (whether or not they completed the survey) were weighted to reflect the U.S. adult population.
  - The weighted screener responses were used to determine the distribution of adults who use antibiotics.
  - The survey respondents were weighted to reflect the distribution of adults who use antibiotics.

- Differences that are noted between segments are statistically significant at the 95% confidence level.
  - When response predictors are listed, the predictors are listed in order of greatest impact as determined through a decision tree analysis.
Summary of Findings
One-quarter of recent antibiotic users may have obtained antibiotics by a means that is considered improper.

- 27% of U.S. adults who have used antibiotics within the past year report that they have used an improper means to obtain an antibiotic.
  - Requested an antibiotic from a health care provider: 14%
  - Obtained an antibiotic from a source other than a health care provider: 7%
  - Obtained a prescription over the phone without an office visit: 12%

- Since many people are unable to correctly identify antibiotics, these percentages may be inaccurate, most likely somewhat overstated.
  - Of the 74 people who requested an antibiotic from a health care provider and were able to name the medication, 6 listed a medication that was not an antibiotic.
  - Of the 35 respondents who obtained an antibiotic from someone else and were able to name the medication, 15 listed a medication that was not an antibiotic.
  - Only 33% of respondents were able to correctly identify five medications as either antibiotics or not antibiotics.
    - 10% identified either Tylenol or Robitussin as an antibiotic.

- Demographic profiles differ for the three types of improper procurement.
  - People requesting an antibiotic from a health care provider tend to be very highly educated and have a high income ($over 100,000), or else be Medicaid recipients.
  - Those who obtained an antibiotic from a source other than a health care provider were more likely to have no health insurance and no established relationship with a health care provider, often lower income minorities living in urban areas.
  - People obtaining antibiotics over the phone are more likely to be middle income or higher (over $50,000), or, if they had lower incomes, to live in a suburban or rural area.
Overall, 33% of adults have used antibiotics within the past year, and many of them have not used them as prescribed.

- 33% of the U.S. adult population reports using antibiotics within the past twelve months to treat an illness.
  - Women are more likely than men to use antibiotics (37% vs. 28%), particularly women between the ages of 25 and 34 (44%).
  - Misperceptions as to what medications are antibiotics may have resulted in inaccuracies in these numbers.

- 8% of antibiotic users prefer to treat an early-stage cold with antibiotics as soon as possible.
  - This preference is frequently motivated by a desire to recover more quickly or to prevent other problems.
    - An aversion to the risk of additional problems may explain why this preference is often found among people who are in poorer health, who do not have the means in their household to transport themselves to medical care, or who need more than half an hour to reach their health care provider.
    - Very low income and a lower level of education are also predictors of this preference.

- A somewhat larger proportion (13%) of parents prefer to treat their child’s early-stage cold with antibiotics as soon as possible.
  - Similarly, it is more common for parents to ask the health care provider for an antibiotic for their child than for adults to ask for one for themselves (21% vs. 14%).
  - A preference for treating a child’s colds with antibiotics is more common among parents who are under age 25, who are minorities, or who have children under age 4.

- 21% of antibiotic users do not always complete an antibiotic prescription; 11% have at times not filled a prescription for antibiotics; and 44% skip one or more doses of a prescription.
  - Young adults, under age 35, are the most likely to not complete or not fill a prescription for an antibiotic.
Misconceptions and concerns about antibiotics are both relatively common.

- Recognition of medications as antibiotics is relatively poor, with only one-third of adults correctly identifying five medications as antibiotics or not antibiotics.
- 45% of antibiotic users think that antibiotics can treat viruses, and many feel various non-bacterial illnesses should almost always be treated with antibiotics.
- Antibiotic users are more concerned about side effect or allergic reactions from antibiotics than from other common medications, and they also feel that antibiotics are one of the most likely types of medications to cause problems if directions are not followed exactly.
- While 84% of respondents say they are very or somewhat aware of antibiotic resistance, two-thirds of them do not think that antibiotic resistance is very common.
  - Furthermore, one-third of those who are aware do not know that antibiotic resistance occurs as often in hospitals or nursing homes as in other places.
  - The lowest levels of awareness about antibiotic resistance occur among African Americans, those with low levels of education or income, and very young adults (under 25).
  - Awareness of antibiotic resistance increases gradually with level of income and education.
In summary, a variety of factors contribute to improper procurement, misuse, and misperceptions of antibiotics.

- Several behaviors decrease with higher levels of education or income:
  - Obtaining an antibiotic from someone other than a health care provider
  - Preferring to take an antibiotic in the first few days of a cold
  - Not completing a prescription
  - Lack of awareness about antibiotic resistance

- Other types of misuse are higher among the more educated and affluent:
  - Requesting an antibiotic from a health care provider
  - Obtaining an antibiotic over the phone

- Younger adults are the most likely to not fill a prescription, to not complete a prescription, and to prefer to give a child an antibiotic for an early-stage cold.
  - Younger adults also tend to be less aware about antibiotic resistance.

- Actions of the health care provider during the course of an office visit have little positive effect on the behaviors studied.

- However, the experience of having a pharmacist give verbal directions for taking medications (in general, not just antibiotics) reduces the chance that a person will not fill a prescription for an antibiotic.

- Being at least somewhat aware of antibiotic resistance makes people less likely to not complete a prescription and less likely to prefer using antibiotics in the first few days of one’s own or a child’s cold.
Improper Procurement of Antibiotics

- Summary of Improper Procurement
- Requested Antibiotic from Health Care Provider
- Obtained Antibiotic from Someone Else
- Obtained Antibiotic over the Phone
Overall, 27% of people who have used antibiotics in the past year have used at least one improper means to obtain the medication.

Summary of Improper Antibiotic Procurement
Past 12 Months

- Requested antibiotic from health care provider (n=914) 14%
- Obtained antibiotic from source other than health care provider (n=916) 7%
- Obtained a prescription over the phone (n=916) 12%

Any of these means: 27%
One in seven people who have used antibiotics in the past year have requested an antibiotic from a health care provider and have almost always received it.

### Requested Antibiotic from Health Care Provider

- **Don’t know**: 50

---

1. Multiple responses accepted; responses of 3 or more listed.
2. Not weighted.
People who are college graduates or have incomes over $100,000 are the most likely to ask their health care provider to prescribe an antibiotic.

- Additionally, people covered by either Medicaid or private insurance have an increased tendency to request antibiotics from their health care provider, compared to those covered by other types of insurance or not covered at all.

</table>
Only 7% of antibiotic users say they have obtained an antibiotic from a source other than a health care provider.

Of the 22 respondents who reported that they obtained an antibiotic from a pharmacy without a prescription, only 3 named an antibiotic as the medication, while 9 named other medications and 10 did not know the name.
In two-thirds of the cases where an antibiotic was prescribed over the phone without an office visit, the health care provider was the one to suggest using an antibiotic.
People with incomes over $50,000, as well as those with lower incomes who do not live in a very densely populated area, are more likely to have antibiotics prescribed for them over the phone.

General Use of Antibiotics

- Use Overall, by Age, by Gender
- Response to Cold
- Response to Child’s Cold
- Prescription Not Filled
- Prescription Not Completed
- Doses Skipped
33% of the adult population has used antibiotics to treat an illness within the past 12 months.

- Use is higher among women than among men, particularly women between the ages of 25 and 34.

### Use of Antibiotics in Past 12 Months

### Use by Gender

- Use is higher among women than among men, particularly women between the ages of 25 and 34.

\[\text{□}/\text{〇} = \text{Higher/lower than the percentage for all adults.}\]

1Based on sample of respondents and potential respondents who did not qualify for study.
Among the relatively few people (8%) who prefer to treat an early-stage cold by taking antibiotics, one-half are motivated by a desire to recover more quickly.

- Lack of knowledge about what antibiotics can treat is associated with preferring to take antibiotics as soon as possible.

Preferred Response to Own Cold in First Few Days (n=903)

- Treat with extra rest, herbal remedies, or non-prescription medications: 65%
- Wait for cold to go away without treatment: 26%
- Take antibiotics as soon as possible: 8%

Reason for Preferring to Take Antibiotics as Soon as Possible (n=70)

- To get better faster: 50%
- To prevent other problems from developing: 24%
- To cure the infection/disease: 10%
- To get better faster and to prevent other problems: 4%
- Other: 12%

Belief about Effectiveness of Antibiotics

- Can treat viruses: 11%
- Don’t know: 19%
- Only treat bacteria: 5%
Predictors of preferring to treat a cold with antibiotics include fair or poor health, very low income, and a lower level of education.

- An inability to transport oneself or have a household member provide transportation to the health care provider is also associated with a preference for taking an antibiotic for a cold.

General Use of Antibiotics
For the early stages of a cold, 13% of parents prefer to give a child antibiotics, as compared to 8% of adults who prefer this treatment for themselves.

- Lack of knowledge about what antibiotics can treat is associated with preferring to give one’s child antibiotics as soon as possible.

---

### Preferred Response to Child’s Cold in First Few Days

- **Treat with extra rest, herbal remedies, or non-prescription medications**: 76%
- **Wait for cold to go away without treatment**: 11%
- **Give antibiotics as soon as possible**: 13%

---

### Have Asked Health Care Provider to Prescribe Antibiotic for Child

- **Yes**: 21%
- **No**: 79%

---

### Reason for Preferring to Take Antibiotics as Soon as Possible

- **To get better faster**: 54%
- **To prevent other problems from developing**: 31%
- **School or day care requires antibiotic prescription**: 0%
- **Other**: 15%

---

1. Child under 18 living at home at least half the time.
2. Too few responses of Don't Know for differences to be statistically significant.
Parents who are very young, who are members of minority groups, or who have children under the age of 4 are more likely to favor antibiotics as a treatment for colds.

**Improper Use of Antibiotics**

APUA
Young people (under 35) and minorities are more likely to not fill a prescription.

- The presence of another person during a visit to a health care provider is associated with a lower likelihood of not filling a prescription.
- Additionally, a history of personal attention from a pharmacist reduces the tendency to not fill a prescription.

<table>
<thead>

45% of antibiotic users think that viruses can be treated with antibiotics.

- At least one-half of respondents think that an antibiotic should almost always be used to treat strep throat, bronchitis, childhood ear infections, and sinus infections.
- A belief that antibiotics can treat viruses is not associated with improper procurement of antibiotics.

**Concerns about Antibiotics**

- At least one-half of respondents think that an antibiotic should almost always be used to treat strep throat, bronchitis, childhood ear infections, and sinus infections.
- A belief that antibiotics can treat viruses is not associated with improper procurement of antibiotics.

- **Expectation that Illness Should Be Treated with Antibiotics**

  (n=917 to 918)

  - Strep throat: Almost always 80%, Sometimes 13%, Almost never 4%
  - Bronchitis: Almost always 59%, Sometimes 28%, Almost never 8%
  - Childhood ear infections: Almost always 58%, Sometimes 30%, Almost never 8%
  - Sinus infections: Almost always 50%, Sometimes 38%, Almost never 11%
  - Childhood ear infections that a doctor says are mild: Almost always 27%, Sometimes 40%, Almost never 28%
  - "The flu": Almost always 24%, Sometimes 30%, Always 45%
  - Sinus pressure: Almost always 11%, Sometimes 37%, Almost never 47%
  - Chest colds: Almost always 14%, Sometimes 43%, Almost never 41%
  - Colds: Almost always 30%, Sometimes 64%, Almost never 1%
Respondents tend to be more concerned about side effects and allergic reactions when taking antibiotics than when taking other types of medication.

- Concern about antibiotic side effects is not associated with improper procurement of antibiotics or preference for treating an early-stage cold with antibiotics.
- 41% of those very concerned about negative effects of antibiotics are less likely to use antibiotics today than five years ago, as compared to 29% of those who are somewhat or not concerned.

\[\square/\bigcirc = \text{Higher/lower than level for antibiotics.}\]
Respondents rated antibiotics as one of the most likely medications to cause problems if directions are not followed exactly.

- Eight in ten respondents think that not exactly following directions for antibiotics is very or somewhat likely to cause problems.
- The possibility of antibiotic resistance was mentioned as a potential problem less frequently than the prospect of not getting better or experiencing side effects and other health problems.

**Problems from Not Taking Antibiotics According to Directions**

1. Illness may persist or worsen: 433 mentions
2. Side effects or other health problems: 169 mentions
3. Become immune to antibiotics/create resistant strains: 131 mentions
4. Problem can reoccur: 86 mentions
5. Allergic reaction: 24 mentions
6. Can overdose: 44 mentions
7. Death: 22 mentions
8. Drug interaction: 19 mentions
9. Get an infection: 13 mentions

---

1 Multiple responses accepted, responses of 10 or more listed.
2 Not weighted.

□/○ = Higher/lower than level for antibiotics.
Of the 84% of respondents who are very or somewhat aware of antibiotic resistance, only about one-third think that it is very common.

- Awareness of antibiotic resistance is not associated with improper procurement of antibiotics.

### Awareness of Antibiotic Resistance
(n=914)

- Not aware: 16%
- Somewhat aware: 35%
- Very aware: 50%

### Where Antibiotic Resistance Is Thought to Occur
(n=774)

- Equally often in hospitals/nursing homes and other places: 66%
- More often in hospitals/nursing homes: 23%
- Almost always in hospitals/nursing homes: 6%
- Don’t know: 4%

### How Common Is Antibiotic Resistance
(n=784)

- Very common: 37%
- Somewhat common: 57%
- Rare: 5%
- Does not exist: 0.1%
- Don’t know: 1%

### What Causes Antibiotics to Become Ineffective

African Americans, people with no education beyond high school, people with very low incomes, and very young adults are less likely than others to be highly aware of antibiotic resistance.

- The low awareness among young adults and high school graduates suggests that primary and secondary schools are not effective in providing information in this area.

</tbody>
</table>
Any awareness of antibiotic resistance decreases peoples’ inclination to not complete a prescription and to prefer administering antibiotics in the first few days of one’s own or one’s child’s cold.

- Awareness does not significantly impact the tendency to improperly obtain an antibiotic or to not fill an antibiotic prescription.
- There was no significant difference between being very aware and being somewhat aware of antibiotic resistance.
Twice as many antibiotic users are very concerned about maintaining a healthy weight than are very concerned about antibiotic resistance.

- When antibiotic resistance is described in terms of family implications, the proportion who are very concerned rises from 26% to 46%.
Health Care Practices
Over 80% of respondents are treated by a doctor or nurse practitioner, walk or drive themselves to office visits, and can reach their health care provider in less than half an hour.
Just over one-half of respondents report that their health care provider follows all recommended patient care practices, and a similar number report that their pharmacist verbally gives instructions for taking medication.

Health care providers’ use of recommended actions is not associated with less improper procurement of antibiotics or more appropriate behavior with prescriptions.

Actions of Health Care Provider
Last Visit for Illness
(n=872 to 873)

- Ask if you had questions: 88% Yes, 11% No, 2% Don’t know
- Ask you to call if not feeling better: 84% Yes, 14% No, 2% Don’t know
- Explain how long it would take to get better: 80% Yes, 18% No, 2% Don’t know
- Sit down at any point: 79% Yes, 19% No, 2% Don’t know

Summary of Health Care Provider Actions
(n=873)
- Yes to all: 56%
- Yes to some: 42%
- No or don’t know to all: 2%

Actions of Pharmacist Last Time
New Prescriptions Was Filled
(n=918)

- Verbally give directions for taking medication: 56% Yes, 43% No, 1% Don’t know

1Asked of respondents who usually seek medical care for illness.
Over three-quarters of respondents say they are in excellent or good health, and over one-half are covered by private insurance.

### Health and Health Insurance of Respondents

#### Health of Respondent
